August complex wildfire

- List of California wildfires from 2003 to 2024
- The August Complex (August-November 2020, Northern California) burned more than 1 million acres

Survival function of acres burned in California wildfires from 2003 to 2024

- Question : How unusual is the August Complex wildfire?
- One can say that such an event can happen once every 20 years...
- however this estimation is based on small sample of observations

Peaks over thresholds

- Let $X_1, \ldots, X_n$ denote the number of acres burned on California wildfires from 2003 to 2024
- We use the following model

$$\lim_{u \to \infty} \mathsf{P}\left(X - u \leqslant x \mid X > u\right) = G(x) \tag{1}$$

$\rightarrow$ Condition $X > u$: "peaks over thresholds"

$\rightarrow$ $Y = X - u$ is the exceedance loss above the high threshold u

Total number of acres burned in California wildfires from 2003 to 2024

Generalized Pareto distribution

- Question: which kind of distribution G can appear in Equation (1)?

Generalized Pareto distribution

- Question: which kind of distribution G can appear in Equation (1)?

Theorem (Gnedenko (1943); Fisher and Tippett (1928))

The limit distribution G in (1) is necessarily a generalized Pareto distribution (gpd):

$$G_{\gamma,\,\alpha}(x) = \begin{cases} 1 - (1 + \gamma x/\alpha)^{-1/\gamma}, & \gamma \neq 0, \\ 1 - e^{-x/\alpha}, & \gamma \neq 0, \end{cases}$$

where $\alpha > 0$, and $1 + \gamma x/\alpha > 0$ when $\gamma \neq 0$.

Fitting a gpd to exceedances

- Recall $X_1, \ldots, X_n$ the number of acres burned on California wildfires from 2003 to 2024

Fitting a gpd to exceedances

- Recall $X_1, \ldots, X_n$ the number of acres burned on California wildfires from 2003 to 2024
- A threshold u, typically chosen as the 0.9 quantile in extreme value theory

Fitting a gpd to exceedances

- Recall $X_1, \ldots, X_n$ the number of acres burned on California wildfires from 2003 to 2024
- A threshold u, typically chosen as the 0.9 quantile in extreme value theory
- A random number N_u will exceed the threshold u

Fitting a gpd to exceedances

- Recall $X_1, \ldots, X_n$ the number of acres burned on California wildfires from 2003 to 2024
- A threshold u, typically chosen as the 0.9 quantile in extreme value theory
- A random number N_u will exceed the threshold u
- Using Equation (1), we assume that the exceedance losses $Y_1, \ldots, Y_n \sim G_{\gamma,\alpha}$, and estimate γ and α using maximum likelihood (Bücher and Segers, 2017)

Fitting a gpd to exceedances

- Recall $X_1, \ldots, X_n$ the number of acres burned on California wildfires from 2003 to 2024
- A threshold u, typically chosen as the 0.9 quantile in extreme value theory
- A random number N_u will exceed the threshold u
- Using Equation (1), we assume that the exceedance losses $Y_1, \ldots, Y_n \sim G_{\gamma, \alpha}$, and estimate γ and α using maximum likelihood (Bücher and Segers, 2017)
- We obtain the log-likelihood function

$$
l((\gamma, \alpha); Y_1, \ldots, Y_{N_u}) =
\begin{cases}
-N_u \ln(\alpha) - (1 + 1/\gamma) \sum_{i=1}^{N_u} \ln\left(1 + \gamma Y_i/\alpha\right), & \gamma \neq 0, \\
\\
\alpha^{-1}\left(N_u(1-u) - \sum_{i=1}^{N_u} Y_i\right), & \gamma \neq 0,
\end{cases}
$$

(2)

which we maximize subject to $\alpha > 0$, and $1 + \gamma Y_i/\alpha$ for all i, when $\gamma \neq 0$

QQ-plot of the fitting: Part 1

- We minimize the minus likelihood function in (2) using the R function 'optim()' from the 'stats' package

QQ-plot of the fitting: Part 1

- We minimize the minus likelihood function in (2) using the R function 'optim()' from the 'stats' package
- We obtain $\hat{\gamma} \approx 0.419$ and $\hat{\alpha} \approx 62\,886$

QQ-plot of the fitting: Part 1

- We minimize the minus likelihood function in (2) using the R function 'optim()' from the 'stats' package
- We obtain $\hat{\gamma} \approx 0.419$ and $\hat{\alpha} \approx 62\,886$
- The quantile function of a gpd is given by

$$Q_{\gamma,\alpha}(p) = \frac{\gamma}{\alpha}\left((1-p)^{-\gamma} - 1\right) \tag{3}$$

QQ-plot of the fitting: Part 1

- We minimize the minus likelihood function in (2) using the R function 'optim()' from the 'stats' package
- We obtain $\hat{\gamma} \approx 0.419$ and $\hat{\alpha} \approx 62\,886$
- The quantile function of a gpd is given by

$$Q_{\gamma,\alpha}(p) = \frac{\gamma}{\alpha}\left((1-p)^{-\gamma} - 1\right) \tag{3}$$

- We consider the QQ-plot

$$\left(Q_{\hat{\gamma},\hat{\alpha}}(\frac{i}{N_u + 1}), Y_{i,N_u}\right), \qquad i = \ldots, N_u,$$

where Y_{i,N_u} denote the i-th ranked observation
- See the plot on the next slide

QQ-plot of the fitting: Part 2

Quantile–Quantile Plot

How unusual is the August Complex wildfire?

- Again, we assume that the exceedance losses $Y_1, \ldots, Y_{N_u} \sim G_{\hat{\gamma}, \hat{\alpha}}$
- Let $x > u$. In our example, x is the number of acres burned in the August Complex wildfire and recall u, the 0.9 quantile

$$
\begin{aligned}
P(X > x) &= P(X > u)\, P(X > x \mid X > u) \\
&= 0.9 \times P(X - u > x - u \mid X > u) \\
&= 0.9 \times P(Y > x - u \mid X > u) \\
&= 0.9 \times \left(1 + \hat{\gamma}\frac{x - u}{\hat{\alpha}}\right)^{-1/\hat{\gamma}} \approx 0.006648479
\end{aligned}
$$
